

Stakeholder input and Assumptions

The primary user is highly intelligent with deep contextual knowledge of the Codebasics platform, its underlying asset types, and the overall folder architecture.

It is strictly assumed that all historical learning assets, video audio tracks, templates, and transcripts are completely in **English only**.

20 TB of One drive data, deeply nested and the oldest is 10 years old

50 Active Users executing **50 search queries daily**, resulting in a compounding volume of **2,500 total system queries every single day** across the company.

All files are open to the user at this time as long as the drive is mapped. No Locked files no security restrictions

Input/Trigger points

User is making a new course and is looking for related artifacts

User wants to search in the assets database for his manager/lead

User needs to update an existing course asset because old content is outdated.

User needs to extract a visual asset or snippet from a course to create a social media post.

Action by Humans

One drive folder structure mapped to the user laptop

User puts in a string say ML as a example

User attempts to cross-reference the old course file against the repository to see what specific slides, videos, or assets can be salvaged versus what needs to be replaced.

User types a phrase they remember being discussed in a previous course video to find the exact timestamp or scene.

Actions by Digital tools (One Drive)

Syncs the 20 TB directory tree to the user's local Windows File Explorer interface, indexing file names.

Executes a basic keyword/character search, looking *only* for the literal characters "M-L" in file titles.

System runs a slow, linear lexical match across deeply nested directories. It completely misses "Machine Learning" folders because the character strings do not match exactly.

It limits its search strictly to literal filename strings.

Pain points

Search takes a very long time, more than 15mins which is a waste of time.

User expects to see ML and Machine learning results the system is not smart

Current system does not remember old searches every search is a new search

Search works sometimes does not work and takes too much time. (The user cannot see inside the media, forcing them to manually open, scrub through, and watch hours of video files just to find a 3-minute clip).
